After doing a basic exploratory analysis of the data, I decided to explore Heat Maps, Pie Charts, and Node and Edge graphs. The first chart, the heat map is a simple to understand measure the percentage of ultra-processed foods by Store and Category. For each category for each store we color classify the percentage of ultra processed foods for each store. This allows us to easily compare different levels of processed foods for each store. The second visualization would be a straight forward compliment to the heat map, this measures the percentage of each F-Pro classification at each score. For the final graph I loaded the data into Neo4J and constructed an interactive graph that lets the user explore categorical relationships with nutrition information. Although this was the most technically complex visualization I created, it requires interactivity from the user to fully grasp the overall concept. I would like to further explore the Heat Map and see if I can further extract out a more compelling story.

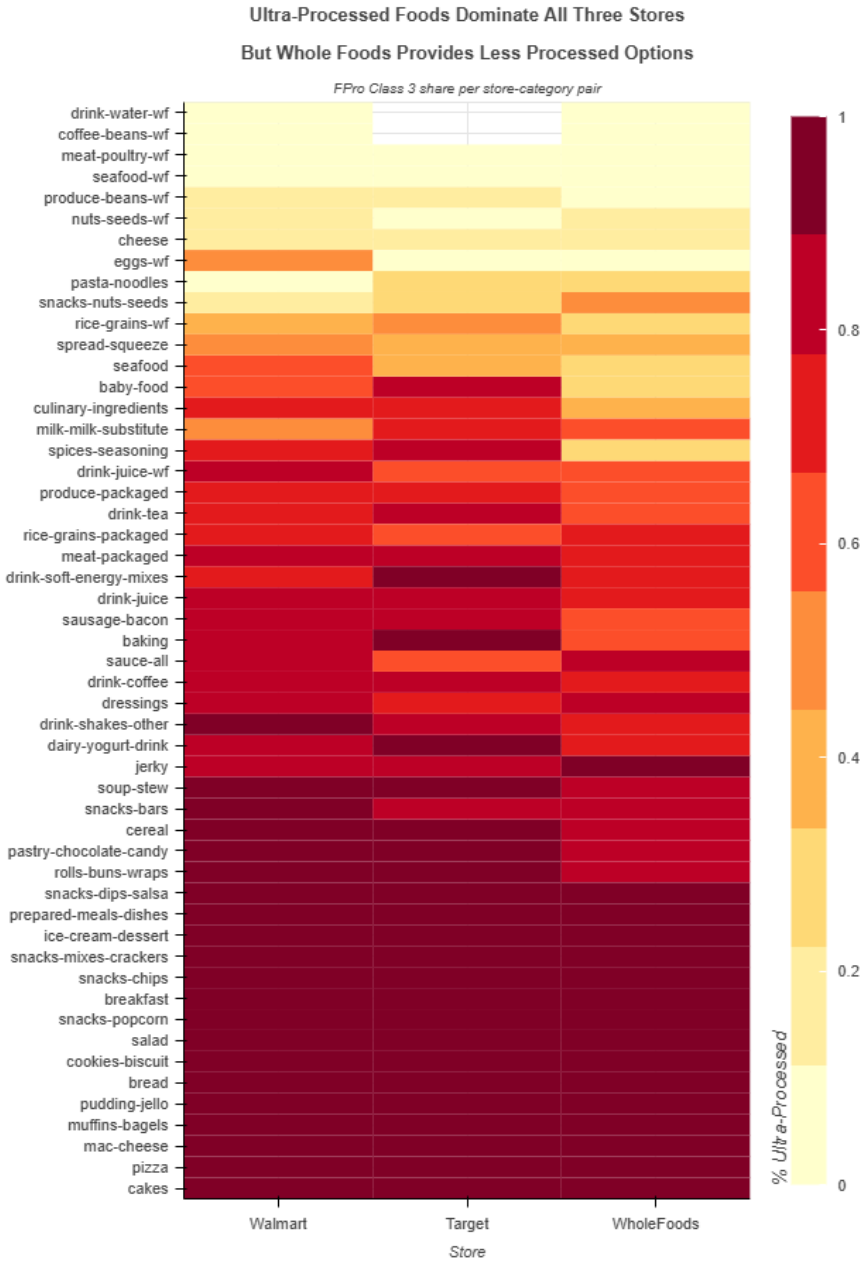

Figure 1: Heat Map displaying categories and Fpro classification percentages for each store

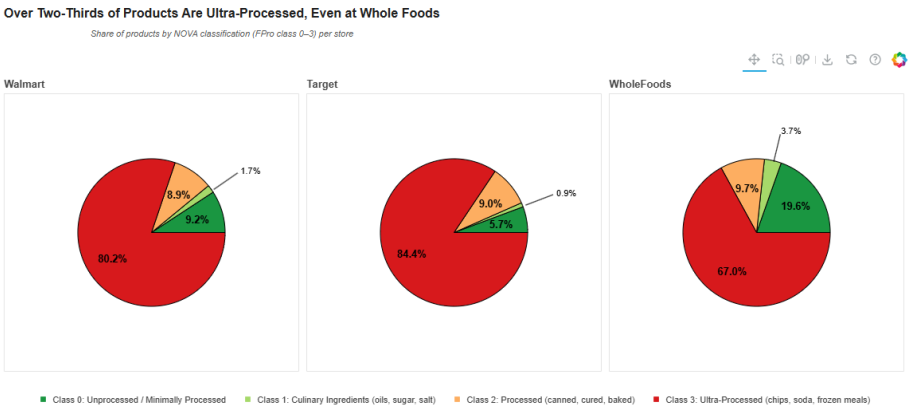

Figure 2: Basic per-store percentages of Fpro classifications

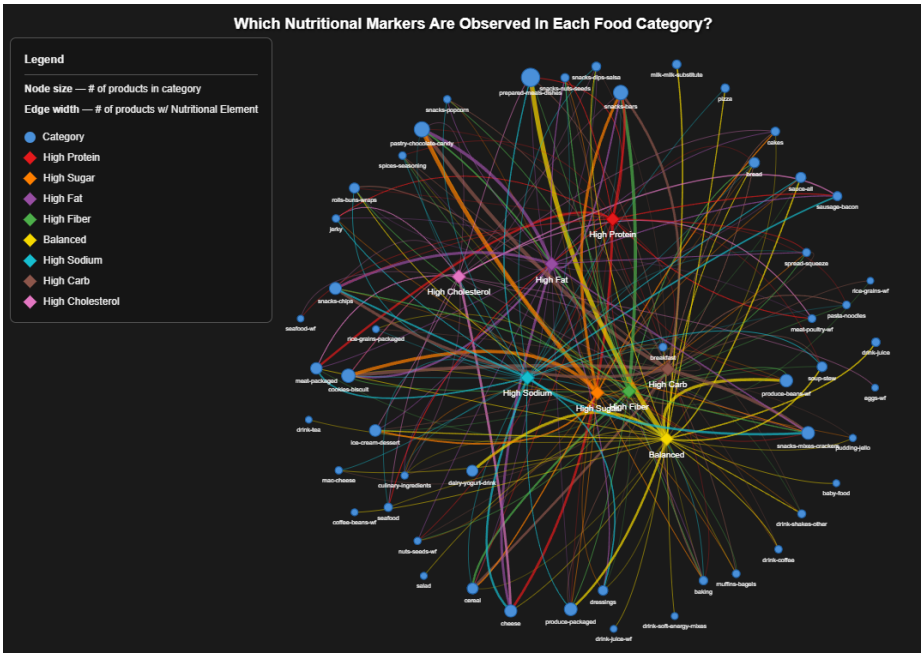

Figure 3: Full Node and edge graph for associations Neo4J associations of categroies and Nutritional Elements

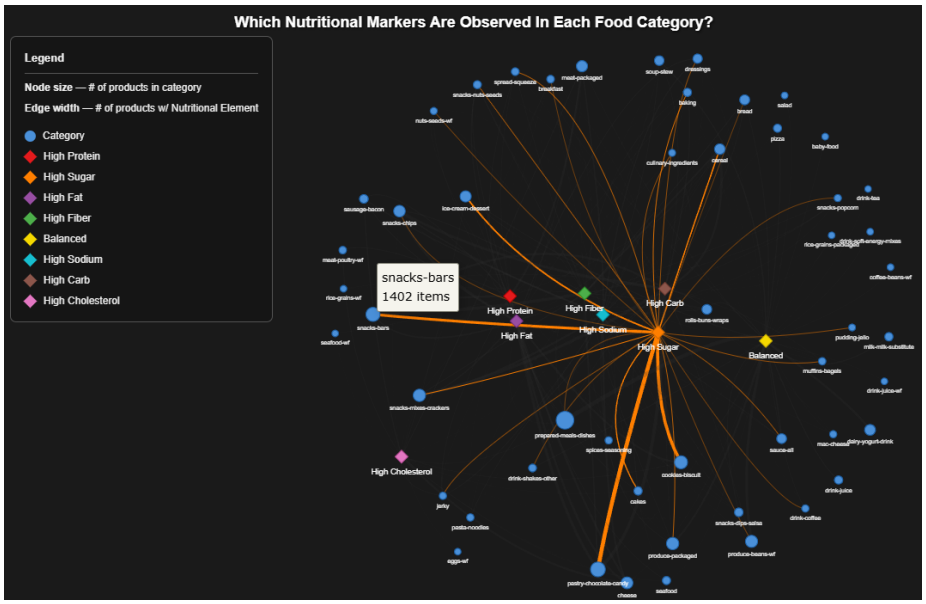

Figure 4: Selecting High Sugar reveals the edges of items that fall into a high sugar nutritional element. The size of the categroy node is a raw measure of the amount of products in the category

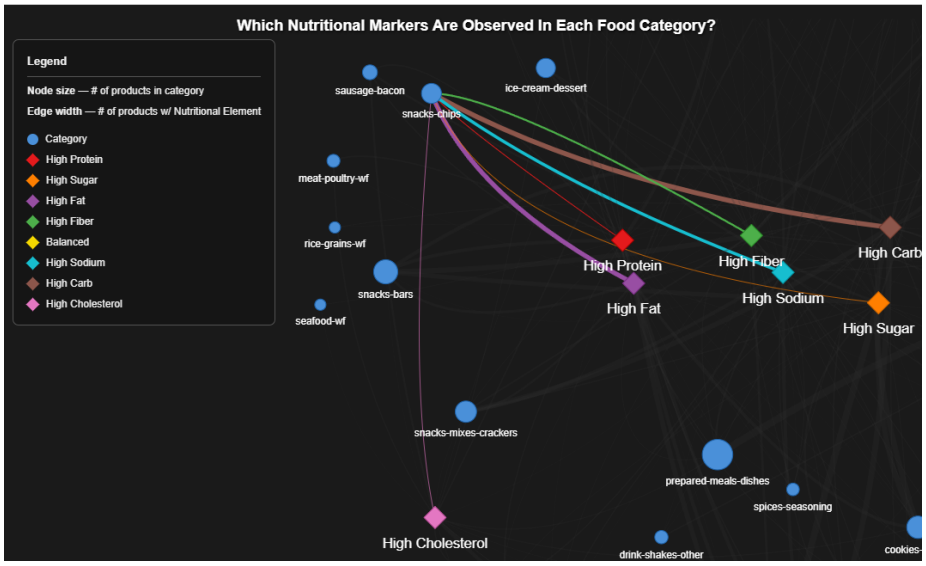

Figure 5: Selecting Snacks-chips category shows that most products contain High fat and High Carb items.
